ABSTRACT:

Introduction: Specialized care barriers are widespread and multifactorial, with consequences for timely access, health outcomes, and equity, especially in rural contexts. This article aims to identify and analyze arrangements for providing specialized care in the Brazilian remote rural municipalities (RRMs).

Methods: This is a multiple-case qualitative case study developed in seven RRM located in the Brazilian semi-arid region. Twenty-two semi-structured interviews were conducted with the public health system managers, complemented by analysis of secondary data from national health information systems. Thematic content analysis was guided by the Integrated Health Service Network attributes related to the provision of specialized care.

Results: Socioeconomic indicators and indicators of availability and accessibility to health services express the context of greater vulnerability of RRM and their respective health regions when compared to states and the country. The analyzed cases do not come close to the RISS constitutive attributes. Various arrangements for the provision and financing of specialized care in the RRM were identified: public provision through an agreement

Keywords:

access to health services, Brazil, integration of health services, rural health services, secondary care.

between managers in the health region, health consortia, public provision in the municipality itself or neighboring municipalities, provision in private health services through direct purchase (out-of-pocket), and telehealth (very incipient). Such arrangements were unable to respond quantitatively and qualitatively to the demand for specialized care. Providing timely specialized care in an adequate place is not achieved, resulting in a fragmented, low-resolution model. The fragility of regionalized networks, aggravated by underfunding of the Brazilian Unified Health System, insufficient logistical support, and computerization of health services, contributes to care gaps and unacceptably long travel times for common specialized procedures, with more severe effects for people residing in the rural areas of the municipalities.

Conclusion: Brazil's disorganization or lack of a systemic response based on regionalized health networks generates several care improvisations. The less structured the RISS, the more informal arrangements are made, with gains for the private sector to the detriment of public health system users.

FULL ARTICLE:

Introduction

Remote rural locations with low demographic density and large territorial extensions experience additional barriers to ensure access to primary healthcare services, which is more critical regarding specialized care¹. The provision of specialized care faces difficulties in financial sustainability, insufficient human resources², and adequate training to work in the context of rurality, even in high-income countries³.

Long distances with high travel costs and waiting times for specialized care are more severe for the inhabitants of rural areas⁴ and have been associated with concentration of specialists in urban clusters⁵. Barriers to specialized care are widespread and multifactorial, with consequences for timely access, health outcomes, and equity in urban and rural contexts⁶. Even so, few countries have established policies aimed at providing accessible specialized care for rural contexts. For example, Italy has a national policy for remote rural areas to guarantee minimum standards of access and avoid specialized care inefficiency, partly provided in small hospitals³. Australia and Canada have small hospitals under the responsibility of states and territories/provinces, and others, such as Spain, do not have national policies for these units in rural areas³.

Communication between primary health care and specialized care is weak in fragmented health systems. Support and logistical systems are not coordinated, aggravating the issues of coherence, quality, security, and access in all care levels⁷. In the Americas, PAHO/WHO proposes the arrangement of Integrated Health Services Networks (RISSs) based on four domains: care model, governance, organization and management, and allocation of

financial resources and incentive system⁷. In Brazil, since 1988, the right to health has been guaranteed by the national constitution. Access to health services must be ensured through the Unified Health System (SUS), guided by the principles of universality, decentralization, comprehensive care, and social participation. The financing, organization and provision of health services by SUS is the responsibility of the three spheres of government: federal, state, and municipal⁸. Political-administrative decentralization in SUS determines the municipality as the sphere responsible for the provision and organization of primary health care in the territories. For specialized care provision, especially in small municipalities, cooperative arrangements between governments that guarantee full access to health are necessary⁹. The 'health regions', defined by national health governance, correspond to the health organization strategy for the provision of services among a set of municipalities. In the health region, the municipality with the greatest diversity of services becomes the headquarters and health reference for others. Health regions are inspired by the classic model of the Dawson report¹⁰ and, therefore, are organized through a hierarchy among services. Furthermore, the regions are planned according to the logic of healthcare networks and organized based on scale, quality and opportunity for access criteria. The provision of services and assistance flows are defined through agreements and pacts between managers of municipalities in the regional health territory. However, the understanding and provision of comprehensive care are compromised, among other factors, by the lack of guidelines guiding the structuring of a model for the provision of specialized care in healthcare networks (RASs)⁹.

According to Dawsonian logic, a minimum scope of actions to promote comprehensive care would be assured in the health

regions, and primary health care provided in each municipality. More complex procedures would refer to health macro-regions (which gather several regions) or even the state capital, depending on the regionalization's design. However, specialized care provision is concentrated in few health regions in the country, generally with greater economic dynamism⁹, and does not cover all primary healthcare requests¹¹. Other issues are the insufficient and heterogeneous provision of specialized services, one of the significant challenges of the SUS¹¹.

This mosaic of problems seems to share a common genesis and, among other aspects, derives from the lack of definition of a model for the provision of specialized care consistent with the production of care in the RISS or RAS, as it was conventionally called in Brazil. This article aims to identify and analyze arrangements for the provision of specialized care in Brazilian remote rural municipalities (RRMs). It is argued that such strategies should be organized per the territories' specificities and that, in the absence of models, informal and dispersed arrangements adopted by managers, users, and professionals tend to dissipate the scarce health resources, exacerbating inequalities and care fragmentation.

Methods

A multiple-case qualitative study on RRM was performed through semi-structured interviews, complemented by analyzing secondary data from national health information systems. In the country, the definition of rural and urban municipalities gained a new typology in 2017¹², in line with OECD and European Union methodologies. This article is nested in a national study on the organization and use of primary healthcare services in Brazilian RRM¹³.

The results of seven RRM located in the Brazilian semi-arid region were analyzed. It is an area marked by water scarcity and low socioeconomic development and is a space of contradictions, with high social inequality¹⁴. The semi-arid region is a vast area concentrated in the Northeast region of the country and includes municipalities in the north of Minas Gerais, in the Southeast region¹⁵. Among the 323 municipalities classified as remote rural in the country, 64 are in the semi-arid (22 in the north of Minas Gerais, 20 in the state of Bahia, and 22 in the state of Piauí).

The RRM in the semi-arid region were first characterized according to socioeconomic, demographic, and health indicators to define the intentional sample of municipalities in the study. Subsequently, the criterion for selecting municipalities that would approach the 'type municipality' was adopted considering these variables, which led to the selection of Morpará and Ipujiara (Bahia), Rubelita and Indaiabira (Minas Gerais), and Rio Grande do Piauí (Piauí). Given the RRM diversity, it was decided to include municipalities with outlier characteristics in the area (Pilão Arcado, due to its above-average population, and Bonito de Minas, due to the lowest GDP per capita).

The territory's classification was adopted in two areas to understand the intramunicipal characteristics: the headquarters, identified as the core; and the rural area, an inland area of the municipality, which corresponds to small and dispersed population groups located in regions far from the headquarters.

Participants and data collection

The study population consisted of 22 respondents: municipal health managers (municipal health secretaries (GM1) and primary healthcare coordinators (GM2) (14) of the seven cases), regional managers (GR) of each of the five health regions to which the seven municipalities belonged (5), and the state primary healthcare coordinator (GE) in each of the states involved (3). These key actors were primarily responsible for the management and organization of the RAS in the SUS, which, according to the Brazilian federative system, establishes the public and universal provision of health services under the responsibility of the three government spheres: federal, state, and municipal.

Interviews were conducted in person, in the respective workplaces, from May to October 2019, lasting from 1 to 2.5 hours, audio-recorded, and fully transcribed. Secondary data from national health information systems were adopted to characterize socioeconomic indicators, the health service network, and specialized care procedures for the seven cases. Procedures performed at the secondary care level were selected to analyze access to specialized tests: echocardiography, colposcopy, and obstetric ultrasound with and without Doppler. Such procedures were selected because they are part of the lines of care for, respectively, systemic arterial hypertension, cervical cancer and prenatal care used as tracer events in the national study, of which this article is part¹³. These data were accessed in the SUS outpatient information system and correspond to the tests carried out for the seven municipalities' citizens from October 2015 to October 2020. A source-destination matrix was drawn up; that is, where each of these procedures was performed for the population residing in the selected RRM.

Data analysis

Thematic content analysis was carried out to produce the results, guided by the attributes of the RISS related to the provision of specialized care⁷: sufficiency of the health services network to provide comprehensive care, provision of specialized services in more appropriate places, integrated management of logistical support, available assistance coordination, integrated information system linking the network's points, sufficient workforce, sufficient funding in line with the RISS targets, and a single governance system for the entire network. The results were presented considering the context of health services and the arrangements identified for the provision of specialized care, within which the RISS attributes are addressed. The authors aimed to ensure the findings' quality and validity by triangulating the information from the interviews and secondary data. It was not intended to judge each municipality but to understand processes in RRM territories through representative settings.

This study was approved by the Human Research Ethics Committee of the Sérgio Arouca National School of Public Health of the Oswaldo Cruz Foundation (no. 2.832.559).

Results

Context: health services in remote rural municipalities

The seven municipalities were distributed over three Brazilian states and comprised five health regions that should provide specialized care actions, mainly in the respective host cities. The characterization presented in Table 1 expresses the context of greater socioeconomic vulnerability of the RRM and their respective health regions when compared to the states and Brazil.

The public provision of primary healthcare services stood out, with high coverage by the Family Health Strategy, the main Brazilian primary healthcare organizational model, with teams consisting of a general practitioner, a nurse, nursing technicians, community health workers, and the oral health team; residual coverage by private health insurance (<2%); and lack of private and public specialist services, which, according to state managers, historically conditioned intermunicipal travels frequently to the state capital and headquarters of the health macroregion to seek specialized care. Interdisciplinary teams (family health support centers) also supported primary healthcare professionals in developing educational and clinical actions (Table 2).

The travel modes to the specialized care varied, and evaluations were unanimous regarding the difficulties in the provision of transport means. People used municipal health transport considered to be insufficient, public transport financed by municipalities or their own resources (in general, city buses scarce and at times incompatible with scheduling visits/specialized tests), or rented vehicles with their resources. Sometimes, travel was a more significant challenge than the provision of specialized care itself, with more unfavorable differences for people living in the rural areas of the RRM, who endured greater distances and out-of-pocket expenses, as they needed to reach the headquarters to subsequently access a means of transport to reach specialized care providers (Table 3).

Distances and the dangerous nature of some routes became more severe the more distant the specialized care provision place, as in the cases of concentration in state capitals. Death could be an outcome depending on the severity of the case.

Also, providing health transport or intercity bus tickets was not

enough. It was necessary to ensure some type of support for their stay ('support homes') when, for example, users were referred to the capital or the headquarters of the health macroregions, especially those from the inland region or who required prolonged treatment. Such costs placed a heavy burden on local budgets, which sometimes interrupted the regular provision of health transport to 'balance' public accounts.

Table 3 shows the distances traveled by residents of the headquarters and rural areas to the leading specialized care providers. The table also indicates the estimated travel times by managers, professionals and users participating in the study whose evaluations consider, in addition to distance in kilometers, road conditions, means of transportation and weather conditions.

Taking as a reference four specialized procedures performed by the SUS (which excludes procedures paid for by the users themselves or via private health insurance plans), the authors identified the municipality that concentrated most of the tests performed in 5 years (October 2015 to October 2020) and the respective distances from the seat of each RRM (Table 4).

Epidemiological parameters were not employed to estimate the sufficiency of the tests shown in Table 4. Also noteworthy is a budget ceiling from federal resources for specialized outpatient care, and procedures paid for by municipalities were often not reported in national information systems. Even so, the insufficiency of some procedures was observed, considering that it is the sum of the procedures performed in the SUS over 5 years. A low number of colposcopies was observed in all municipalities (except Morpará). In three cases, most examinations were carried out in the state capital, with distances reaching almost 800 km. The echocardiogram performance pattern was even more restricted. The shortest distance was 217 km and the longest 788 km, and in none of the cases was the main place of performance the health region headquarters. Obstetric ultrasound showed essential differences between approved and presented, indicating municipal contributions in test costs and performance in the city itself or the health region headquarters, which is reflected in lower distances covered for the service. The Doppler ultrasound, indicated in high-risk pregnancies, was not carried out or performed with municipal resources and not registered in the information system (Table 4).

[†] Tests approved and paid for according to the budget forecast provided for in the Agreed Integrated Programming via transfer MAC (medium and high-cost/complex ambulatory care).

[‡] Number of tests carried out in the period that, if higher than that provided for in the Agreed Integrated Programming, are financed through municipal resources.

Data sources: Outpatient Information System, of the Informatics Department of the Brazilian Unified Health System; State Department of Roads and Highways Bahia, Minas Gerais and Piauí (for distances); research database, based on information from managers, professionals and users.

Arrangements for the provision of specialized care

Various arrangements were identified for the provision and financing of specialized care in the RRM, with different degrees of implementation, namely public provision through Agreed Integrated Programming (PPI) in the health region, health consortia, public provision in the municipality itself or neighboring municipalities, care in private health services through direct purchase (out-of-pocket expenses), and telehealth.

Public provision of specialized care through Agreed Integrated Programming in the health region: The main instrument for allocating financial resources for the provision of specialized care

in the RRM was the PPI, which was a negotiation instrument between managers in a health region to decide which municipalities/public and private service providers SUS financial resources would be allocated to ensure specialized procedures. According to the regionalization design, specialized care services should concentrate primarily on the respective health regions to guarantee more timely access and the services of greater technological complexity in the health macro-regions, which did not occur in many cases.

Taking as a reference some procedures presented in Table 4, it was observed that the public provision of specialized tests routinely

requested to monitor cervical cancer, arterial hypertension, and prenatal care did not have as the main reference the city headquarters of the health region, in which, in general, the provision of health services negotiated via PPI should be concentrated. For some tests/specialists, despite distances of almost 800 km (rural area of Pilão Arcado), most referrals were made to the state capital. Sometimes, resources from special funds (parliamentary amendments) were invested in ambulances for user travel.

The long distances between the municipalities that provide specialized care and the RRM (Table 3), and the irregular provision of transport implied lack of assistance and, currently, inequalities according to the managers' assessments. Sometimes, it became more 'advantageous' for the user to pay out-of-pocket, especially for low-cost services performed in the municipality of residence or neighboring municipalities.

Distance to the municipalities with most of the specialized care provision evidenced more significant difficulties of access for the rural inhabitants. They sometimes had to travel routes exceeding 100 km (Ipupiara, Bonito de Minas, and Pilão Arcado) to the RRM headquarters and, subsequently, traveled to specialized reference services (Table 3). Also, as assessed by the informants, the provision of dispersed specialized care among various municipalities in the health regions overly encumbered health transport logistics.

The costs of tests and specialized visits in the country were set by the Ministry of Health and were outdated in relation to the medical market, considering the scarcity and low diversity of providers in the regions studied. Consequently, managers negotiated the purchase of services through agreements with private providers. The provider was contracted for the value of resources and supplied some procedures (above the fixed price).

In the cases studied, specialized care scheduling was performed, in general, by the user with a medical referral, in the municipal health secretariats. As there was no computerized system for scheduling appointments and specialized tests in the primary healthcare units, users living in the rural areas of the RRM needed to travel to the municipal headquarters, meaning more significant expenses, in particular for the most impoverished population.

Public provision of specialized care via Health Consortia: Two types of health consortia were identified. The municipalities of Minas Gerais had intermunicipal health consortia (CIS), established to provide specialized care that complemented the insufficient provision via PPI. The CISs had regional coverage and were financed through public resources raised by the municipalities. A 'menu' of services was provided by CIS in private providers and used according to the schedule made by the municipalities. As a result of the purchase of procedures linked to the Ministry of Health's values, many private providers were not interested in providing their services, thus limiting diversity.

In general, specialized care provision via CIS was reserved for urgent situations and more significant access difficulties. The regional manager affirmed that the CIS strategy was essential to

the municipalities as it ensured part of the specialized care not supplied via PPI and guaranteed some scale in the purchase of services at better prices.

In Bahia, regional health polyclinics have been implemented through interfederative health consortia since 2017, with voluntary adherence to the municipalities, to provide specialized care services in the health regions. Contrary to the CIS model in Minas Gerais, the polyclinics had state equipment, direct specialized care providers, with management and financing shared between municipalities and the state. The objective was to guarantee specialized care provision through care flows coordinated by the primary health care and health transport by minibuses, a critical resource for the RRM. According to the state manager of Bahia, the concern with the integration between primary health care and specialized care was mentioned only in the initiative to implement regional polyclinics. In the other evaluations, care coordination was assumed non-existent as there were no shared electronic medical records. Some transit of clinical information was incumbent upon the user themselves or, as in small municipalities, primary healthcare managers and professionals seeking information about care provided in other services. Community health workers were identified as the primary informant of a user's situation, allowing some care continuity.

In Ipupiara, the municipal manager considered that there was no interest on the part of all municipalities, as the municipal financial contribution for maintaining the polyclinics was high. Political alignment between municipal and state governments, too, was identified as a determining factor for adherence to CIS.

Public provision of specialized care in the municipality itself or neighboring municipalities: While timely and discontinuously, depending on the availability of municipal financial resources, to some extent RRM provided specialized care at their headquarters through direct purchase of private services (clinics or professionals). Such an organizational option aimed to cover the insufficient provision of services via PPI, especially those with greater demand and lower cost, such as obstetric ultrasound. Also, a popular and political appeal was noted for the provision of specialized care in the territory itself, mainly due to the difficulty of traveling to other municipalities. A municipal manager said there was an understanding that it would not be necessary to provide specialized care in RRM, but the managers were pressured and sometimes met the political interests and concerns of the population.

In Indaiabira, the municipality adhered to the CIS and entered into agreements with private clinics in the municipality of the health region, with its resources, because it was impossible to meet the specialized care demands even with CIS and PPI.

In Ipupiara, the municipal manager hired a psychiatrist and an orthopedist. In addition, the manager provided ultrasound and X-ray tests in the municipality, paid for with municipal resources. Morpará provided psychiatric care to users referred by primary healthcare teams. The same professional was also a cardiologist and sometimes met the demand for surgical

risk. More recently, an ultrasound device had been purchased, although the problem of a professional for the tests remained.

Ultrasound was also available in Pilão Arcado, according to the respondents' report and secondary data (Table 4). A contracted doctor performed the tests every 2 weeks. Rio Grande do Piauí municipal managers said ultrasound tests were provided biweekly, with weekly appointments with a cardiologist (not shown in Table 4, which shows a low number of obstetric and Doppler ultrasounds in the municipality itself).

Care in private health services through direct purchase (out-of-pocket): Users resorted to out-of-pocket payment to speed up the care itinerary due to the scarce specialized care provision, prolonged time, or even distance to access some appointments and procedures via the public system.

Primary healthcare professionals recommending users to seek, when possible, private health services to carry out visits and specialized tests through direct disbursement to shorten waiting times were commonly reported. In some cases, the community itself and health professionals were mobilized to obtain resources to finance the procedures.

In some cases, municipal management encouraged seeking private services, intermediating discounts, indicating well-known professionals, paying for transportation, or some other subsidy in a nearby municipality. In Ipujiara, transport lines were created to meet the demand for private health services in neighboring cities.

Many users reportedly did not even seek the SUS, turning directly to private providers because they already knew the hardships or impossibilities of public road access.

Telehealth: Minas Gerais municipalities had telehealth services in cardiology, and teleconsulting was hardly used. Electrocardiograms seemed to be the most frequent test. Bahia state management reported that electrocardiogram telediagnosis and, more recently, teledermatology were implemented in the state, including purchasing equipment for the poorest municipalities. Rio Grande do Piauí (and municipalities in the health region) did not use telehealth, or the use was limited to professional training and training activities.

The respondents did not indicate routine telehealth use by health professionals for several reasons: insufficient internet and computers, mainly in primary healthcare services in rural areas, low adherence by professionals, lack of technical support from regional and state administrations, delay in responding to teleconsulting, and technical difficulties of municipal management to implement and use some telehealth instruments. While federal policies for the computerization of primary healthcare services have been reported, they have been insufficient to achieve universalization of this process. There was no quality internet access, and, in most cases, the provision was the responsibility of each RRM.

Table 5 presents a synthesis of the results according to the RISS attributes⁶ and definitive statements by the key informants who give density to the study's findings.

Table 5: Summary of results and expressive statements, according to attributes of the Integrated Health Services Networks – remote rural municipalities, semi-arid region, Brazil, 2019

RISS attribute	Summary	Expressive statements
Sufficiency of the health service network to provide comprehensive care	<p>Insufficient and inefficient provision of specialized care by the public network</p> <p>Extended waiting time for specialized care</p> <p>Long distances between municipalities providing specialized care and the RRM</p>	<p><i>Really insufficient, because we have been without a psychiatrist for a long time ... neurologist, we have many difficulties, it is only one appointment per month; sometimes there's not even a pediatric neurologist, ... tomography is only once a month ... resonance is only once a month ... People come here to ask, and there's nothing we can do. (GM1 – Pilão Arcado, Bahia)</i></p> <p><i>Let's say I have someone in need of a test to have surgery. Sometimes, when he finishes preoperative tests, a year has passed, and she has to go back and do the tests again. (GM1 – Rio Grande do Piauí, Piauí)</i></p> <p><i>The distances between municipalities are enormous, and this people's access to mainly medium- and high-complexity health services. Structuring this flow here in the region is very challenging for us. This is also found within the municipality. We have municipalities with some locations more than 100 km away from the headquarters. (GR – Ibotirama, Bahia)</i></p>
Provision of specialized care in more appropriate places	<p>Dispersed specialized care services: part performed at the regional headquarters (most appropriate) and part at the headquarters of the macroregion and in the state capital (long distances)</p> <p>Residual and discontinued provision provisioned in the RRM</p> <p>More significant inequalities for rural RRM residents</p>	<p><i>Some pediatricians come to the municipality, which I think is practically unnecessary, but the population likes to have the specialist here: 'Ah, there are no specialists in Rubelita'. However, we have references, we have a network that works, but managers think it's cool when we have [a specialist in the municipality]. The mayor likes it: 'A city of 6,000 inhabitants has a psychiatrist, a gynecologist, and ultrasound'. We have an expensive ultrasound device that is not operating and a very costly specialized professional. (GM2 – Rubelita, Minas Gerais)</i></p>
Integrated management of logistical support	<p>Insufficient health transport and inadequate to (bad) road conditions</p> <p>Scarce public transport and timetables incompatible with scheduling appointments and tests</p> <p>Private, improvised, and unsafe transport</p> <p>Support homes for out-of-home care (federal and mostly municipal resources)</p>	<p><i>Sometimes you can't travel on the road because of the sand, and the ambulance is low. We've had very complicated situations where we did not get the SAMU [emergency mobile care service] release, and the nurse came with a patient on top of an open car. The patient has a cardiac arrest and was resuscitated on the road. So, it's a complicated situation in which, sometimes, the patient dies. (GM2 – Morpará, Bahia)</i></p> <p><i>Our roads are not duplicated. These municipalities' access to Teresina [capital] is through a dangerous road, known as the 'death road'. Many accidents occur every week. (GM2 – Rio Grande do Piauí, Piauí)</i></p> <p><i>In Teresina [capital], we have a boarding house. Moreover, we have a specific person to facilitate access to clinics and hospitals. A health vehicle is available for them there. The patient does not have an expense because we pay for the trip from here to Teresina by van. The patient gets there, and there is a specific person to walk with them. (GM1 – Rio Grande do Piauí, Piauí)</i></p>
Care coordination and integrated information system linking network points	<p>Lack of interprofessional communication between primary health care and specialized care;</p> <p>Lack of integrated medical records between services at different care levels</p> <p>Lack of systems for scheduling specialized care appointments and tests in primary healthcare services</p> <p>Incomplete computerization of primary health care and inexistent in other care levels</p> <p>Users and some professionals responsible for clinical communication</p> <p>Lack of care continuity assurance</p> <p>Residual telehealth use</p> <p>Irregular feeding of SUS information systems</p>	<p><i>Look, for me, rare exceptions are counter-referrals from specialized services, whether hospital or secondary care for PHC. When it happens, it is not a care plan that primary care receives; it receives as follows: 'follow a diet, for example, or take a light walk'. It does not receive a care plan for that patient, so there is no communication. (GR2 – Januária, Minas Gerais)</i></p> <p><i>There are some things. We have some pregnant women and some diseases that require primary care and are monitored. Now, we can't cope with heart diseases. We don't have a computerized system to keep up with this specialized service. (GM1 – Morpará, Bahia).</i></p> <p><i>The CHW visits the families' home and checks whether the family went to the doctor, the child got the vaccine, whether there is a pregnant woman in the house, and a problem in that household. The CHW is essential, as he passes all the information about the families to the team. (GM2 – Bonito de Minas, Minas Gerais)</i></p> <p><i>In early 2016, this resource [for telehealth] was agreed with Floriano [headquarters of the health region], but then Floriano stopped. With management change, you know that professionals change. Everything changed, and no one was updating anymore. Telehealth is not currently working. (GM2 – Rio Grande do Piauí, Piauí)</i></p>
Sufficient workforce	<p>Insufficient number of specialists in RRM and health regions</p>	<p><i>The most severe thing we see regarding health is the availability of specialists, who are still very centralized, and we still have few professionals working in these [rural] regions. Most specialists are in large centers. So, inevitably, people living in these locations must travel to</i></p>

		<i>large centers to have specialized care. (GE – Bahia)</i>
Sufficient funding aligned with the RISS and governance goals	<p>Insufficient federal funding and burden on municipal budgets</p> <p>Various arrangements for the provision and financing of specialized care in the RRM</p> <p>PPI – main instrument for allocating financial resources for the provision of specialized care</p> <p>Direct user disbursement</p> <p>Strong dependence on private health services and submission to market values</p>	<p><i>We can partner with private clinics for a discount, 10%, 20%, it already helps, not considering the availability of calling the clinics and scheduling an appointment or a test. (GM2 – Ipupiara, Bahia)</i></p> <p><i>For example, when the doctor requested an MRI. We have such a test with the SUS in the municipality, and it is an annual resonance. So, how can I tell the patient who is already waiting? Here we organize bazaars and food stands. In June, we had a June party with the team to raise funds for a patient's test. (GM2 – Indaiabira, Minas Gerais)</i></p> <p><i>We have direct accreditation with an orthopedic clinic because it is one of the most significant demands, and we pay this separately. We also have a cardiology clinic that is one of the most significant demands here in the city. All paid for with the municipality's resources. (GM1 – Indaiabira, Minas Gerais)</i></p> <p><i>The mayor has focused a lot on health, but the private sector has stood out. However, even realizing that most tests, both in quantity and price, are in the private sector in Irecê [neighboring city], Ipupiara sends many people to Irecê. Vans even make weekly lines. The ticket is expensive, but it pays off for the population because everyone who goes there likes the private service. (GM1 – Ipupiara, Bahia)</i></p>

CHW, community health worker. GE, state manager. GM, municipal manager. GR, regional manager. PHC, primary health care. RRM, remote rural municipality. PPI, Agreed and Integrated Programming. RISS, Integrated Health Services Networks. SMS, municipal health department. SUS, Unified Health System.

Discussion

The results indicate that the analyzed cases were not close to the RISS parameters and attributes, a situation currently found also in other Latin American countries, whose health systems are characterized by fragmentation and weak network performance⁷. Various modalities for the provision and financing of specialized care in the RRM were identified, with public and out-of-pocket resources unable to respond quantitatively and qualitatively to the demand for specialized care integrated with networks.

The cases presented are made up of municipalities and health regions vulnerable in several aspects, without the economic dynamism that acts as a determinant for the attraction of specialized professionals¹⁶ and without national policies for regulating the health workforce, especially concerning medical specialties¹⁷. On the other hand, the assessment was unanimous on the insufficiency of federal and state resources compatible with the conformation of RISS, which overloads the meager municipal budgets and conditions an inefficient, uncoordinated, and discontinuous specialized care provision pattern undertaken locally.

In the context of this study, timely provision of specialized care in an adequate place was not achieved, resulting in a fragmented, low-resolution model. The fragility of the regionalized health networks, aggravated by SUS underfunding, confers care gaps and unacceptable commuting to undergo basic procedures (such as colposcopy and echocardiogram). Prolonged efforts and long times to achieve health care in general – more severe in rural contexts – can also lead to the direct search for private care with out-of-pocket payment, as found in this study, or even more accessible care alternatives such as pharmacies¹⁸.

Such evidence takes on more dramatic contours in the context of rurality, due to the socioeconomic vulnerability of the population

and municipalities, insufficient resources and health equipment in the regions and great distances to be covered. Factors such as isolation, road quality, and climatic conditions have a bearing on the decision to move to obtain health care⁴. All the mapped difficulties do not favor access and can cause discontinuity, delayed and unrealized care, and therapeutic opportunity loss^{19,20}.

The experience of regional polyclinics in Bahia, via CIS, with cofinancing and leadership from the state management, seems to be an arrangement more suited to the provision of specialized care from a regional perspective. Furthermore, it improves care coordination by primary health care and increases access to specialized care by offering health transport for the population to travel to the service¹¹. A challenge would be widespread support and political gains from specialized care provision in the city itself or initiatives by the local manager, despite the dissonance regarding health needs, as often seen in other contexts³.

In Latin American countries, there are incipient studies on the relationship between transport and health, and policies aimed at mobility, which, when they exist, are mainly focused on urban environments²¹. Health transport is an essential component of logistical support to access specialized care and did not obey clinical and organizational rationality – now provided by the municipal management without assured continuity and sufficiency, now at the expense of the users themselves and with spending incompatible with household income, in an unsafe and improvised fashion. The context of insufficient or absent health transport is also that of low investment in infrastructure (unpaved roads and insufficient public transport) and the lack of other public policies. In this sense, while geographic location plays an essential role in determining access to health services, it should not necessarily translate into inequities, insofar as policies and actions for improving rural health are more effective if they address the set of vulnerabilities affecting these populations¹⁸.

The authors could not identify integrated information systems linking the RISS points, such as shared electronic medical records. The precarious computerization of the primary healthcare services and systems for scheduling the specialized care caused yet more travel for users, which, for rural residents, represented a barrier preceding visits or tests. In a fragmented network, the impossibility of communication, coherence, and low cooperation between primary health care and specialized care²² can result in scheduling unnecessary specialized procedures that cause dissatisfaction to users when they have to postpone their routine activities to attend health services²³, especially among older adults leaving their comfort area¹, and dissipate the already insufficient health resources.

The incomplete primary healthcare computerization draws other problems, which lead to the underutilization of telehealth, a strategic resource in remote areas. In Australia, telehealth also lends itself to specialized visits accessed by the user and is reimbursed by public insurance for amounts higher than the face-to-face visit³.

The development of telemedicine strategies in remote areas can improve access to specialized care and avoid preventable hospitalizations, an investment target in many countries^{3,4}. Also, the availability of telephone contact with health services for rural residents, an easily accessible measure, could improve obtaining clinical guidelines and general information for access to care¹⁸, which was not observed in this study.

Despite the previous municipal efforts to resource specialized care, the failure to feed into national systems hinders monitoring of the sufficiency and adequacy of procedures according to epidemiological parameters and sizing the financial and human resources necessary for planning RISS⁷.

It is noteworthy that the RRM tend to present a more fragile and vulnerable governance system to political party harassments to the detriment of technical-sanitary issues in constructing the RISS²⁴. This feature compromises care flows and transfers the responsibility for constructing alternative therapeutic itineraries to users, often with iatrogenic results.

Finally, the greater the dispersion associated with lower population density and longer commuting times to access health care, the greater the need for integrated, comprehensive care in primary health care. The concentration of specialists in urban centers results in dependence of rural populations on primary healthcare providers who, sometimes, develop an expanded scope of practices without adequate training and infrastructure⁶, a priority field for interventions. The resolution of primary health care can also be increased through the incorporation of areas such as mental health²⁵, access to pharmaceutical care at home²⁶, e-health interventions²⁷, combination and integration of telemedicine and home visits carried out by health professionals health²⁸, drive in-drive out and fly in-fly out models²⁹, among others. No less important is recognizing that the insufficient and discontinuous provision of health professionals in remote rural municipalities, especially doctors, threatens the sustainability and maintenance of

health care. This is a global problem for rural areas in which policies to reduce scarcity involve measures at the individual and contextual level, such as the establishment of medical schools in rural areas that contribute to the improvement of the infrastructure of rural health services, and enable the involvement of local communities and promotion of daily experiences of doctors and students with the reality of rural medicine³⁰.

Limitations

This study considered the experience of managers at various levels of the health system of the Brazilian semi-arid territory, whose perceptions and evaluations were synergistic as to the challenges for the provision of specialized care in RRM, caused by local and regional characteristics, which can be different from other rural scenarios, such as in the Amazon region³¹. The experiences of other key actors, such as users, were not considered, although secondary data such as the local production of specialized exams can confirm the barriers to access to specialized care.

Conclusion

In rural Brazil, the disorganization or lack of a systemic response based on regionalized networks generates several care improvisations. The less structured the RISS, the more informal the arrangements that emerge, with gains for the private sector to the detriment of SUS users.

The cases studied bring about essential contextual elements for planning the provision of systemic and regional specialized care at the risk of defining innocuous proposals for the reality of RRM in the Brazilian semi-arid region. Considering the various challenges that condition the concentration of services and health professionals in urban centers, some possible arrangements are indicated to streamline specialized care provision in these contexts.

The first concerns the mobility capacity of RRM users. Public and safe integrated health transport systems are a crucial element for access to health, as is the definition of care flows that correspond to real and feasible routes within the municipalities (headquarters and rural area) and in the health region.

Another action refers to the increase in the resolving capacity and linking users to primary health care, including urgent care and investments in information and communication technologies that enable the clinical coordination and streamlining of the provision of specialized resources via telehealth to professionals and users.

Strengthening social participation levels and collegiate regional management bodies are strategies to mitigate intervening factors, such as political and private interests, which hinder organized and reasonable provision of specialized care. Regional governance must combine policy and technique to retract mechanisms based on users' accountability to seek the necessary resources for health care, which are not representative of SUS universalizing precepts.

While such organizational strategies are fundamental in different contexts, it is argued that they are crucial to enable access to specialized care in RRM since these populations have no other care options and are exposed to more significant inequalities.

Social policies must provide for specific actions for the RRM, notably for their rural areas, without which health actions will be less effective. To this end, they must be accompanied by sufficient federal funding for the establishment of RISS and the strengthening of collaborative regionalization between municipalities, from a Dawsonian perspective that, while not representing anything new, has barely advanced in the country and seems to be outside the current agenda of political priorities.
